**POLA**  
Point-of-Load Alliance

## 1. Introduction

The PTH/PTV family of non-isolated, wide-output adjust power modules from Artesyn Technologies are optimized for applications that require a flexible, high performance module that is small in size. These products are part of the “Point-of-Load Alliance” (POLA), which ensures compatible footprint, interoperability and true second sourcing for customer design flexibility. The POLA is a collaboration between Artesyn Technologies, Astec Power and Texas Instruments to offer customers advanced non-isolated modules that provide the same functionality and form factor. Product series covered by the alliance includes the PTHxx050 (6 A), PTHxx060 (10 A), PTHxx010 (15/12 A), PTHxx020 (22/18 A), PTHxx030 (30/26 A), PTHxx040 (50/60 A), PTVxx010 (8 A) and the PTVxx020 (16/18 A).

From the basic, “Just Plug it In” functionality of the 6 A modules, to the 30 A rated feature-rich PTHxx030, series these products were designed to be very flexible, yet simple to use. The features vary with each product series. Table 1 provides a quick reference to the available features by series and input bus voltage.

For simple point-of-use applications, the PTHxx050 series provides operating features such as an on/off inhibit, output voltage trim, pre-bias start-up (3.3/5 V input only), and over-current protection. The PTHxx060 (10 A), and PTHxx010 (15/12 A) series add an output voltage sense, and margin up/down controls. The higher output current, PTHxx020 and PTHxx030 series also incorporates over-temperature and shutdown protection. All of the products referenced in Table 1 include Auto-Track™.

This is a feature unique to the PTH/PTV family, and was specifically designed to simplify the task of sequencing the supply voltage in a power system. These and other features are described in the following sections.

SERIES	INPUT BUS	I <sub>OUT</sub>	ADJUST TRIM	ON/OFF INHIBIT	OVER-CURRENT	PRE-BIAS STARTUP	AUTO-TRACK™*	OUTPUT SENSE	THERMAL SHUTDOWN
PTVxx010	3.3/5 V	8 A	•	•	•	•	•		
	12 V	8 A	•	•	•	•	•		
PTVxx020	3.3/5 V	18 A	•	•	•	•	•	•	•
	12 V	16 A	•	•	•	•	•	•	•

Table 1 - Operating Features by Series and Input Bus Voltage

### RoHS Compliance Ordering Information

PTV12020WAH

To order Pb-free (RoHS compatible) through-hole parts replace the mounting option ‘H’ with ‘D’, e.g. PTV12020WAD.

\*Auto-track™ is a trade mark of Texas Instruments

## 2. System Interface Information

### 2.1 Input Capacitor

The required input capacitors are a 22  $\mu\text{F}$  ceramic, and a 560  $\mu\text{F}$  electrolytic type. For  $V_o > 2.1\text{ V}$  and  $I_o \geq 11\text{ A}$ , the 560  $\mu\text{F}$  capacitance must be rated for 1200 mA rms ripple current capability. For other conditions,  $V_o > 2.1\text{ V}$  at  $I_o < 11\text{ A}$  and  $V_o \leq 2.1\text{ V}$  for all loads, the ripple current rating must be at least 750 mA rms. Where applicable, Table 1 gives the maximum output voltage and current limits for a capacitor's rms ripple current rating.

The 22  $\mu\text{F}$  X5R/X7R ceramic capacitor is necessary to reduce both the magnitude of ripple current through the electrolytic capacitor and the amount of ripple current reflected back to the input source. Ceramic capacitors should be located within 0.5 inch. (1.3 cm) of the module's input pins. Additional ceramic capacitors can be added to reduce the rms ripple current requirement for the electrolytic capacitor.

Ripple current (Arms) rating, less than 100 m $\Omega$  equivalent series resistance (ESR), and temperature are the major considerations when selecting input capacitors. Unlike polymer-tantalum capacitors, regular tantalum capacitors have a recommended minimum voltage rating of 2 x (max. dc voltage + ac ripple). This is standard practice to ensure reliability. Only a few tantalum capacitors were found to have sufficient voltage rating to meet this requirement. At temperatures below 0  $^{\circ}\text{C}$ , the ESR of aluminum electrolytic capacitors increases. For these applications, Os-Con, polymer-tantalum, and polymer-aluminum types should be considered.

### 2.2 Output Capacitance (Optional)

For applications with load transients (sudden changes in load current), regulator response benefits from external output capacitance. The recommended output capacitance of 330  $\mu\text{F}$  allows the module to meet its transient response specification. For most applications, a high-quality computer-grade aluminum electrolytic capacitor is adequate. These capacitors provide decoupling over the frequency range, 2 kHz to 150 kHz, and are suitable when ambient temperatures are above 0  $^{\circ}\text{C}$ . For operation below 0  $^{\circ}\text{C}$ , tantalum-, ceramic-, or Os-Con-type capacitors are recommended. When using one or more non-ceramic capacitors, the calculated equivalent ESR should be no lower than 4 m $\Omega$  (7 m $\Omega$  using the manufacturer's maximum ESR for a single capacitor). A list of preferred low-ESR-type capacitors are identified in Table 2.

#### 2.2.1 Tantalum Capacitors

Tantalum-type capacitors can only be used on the output bus, and are recommended for applications where the ambient operating temperature can be less than 0  $^{\circ}\text{C}$ . The AVX TPS, Sprague 593D/594/595 and Kemet T495/T510 capacitor series are suggested over many other tantalum types due to their higher rated surge, power dissipation, and ripple current capability. As a caution, many general-purpose tantalum capacitors have considerably higher ESR, reduced power dissipation, and lower ripple current capability. These capacitors are also less reliable as they have reduced power dissipation and surge current ratings. Tantalum capacitors that have no stated ESR or surge current rating are not recommended for power applications.

When specifying Os-con and polymer tantalum capacitors for the output, the minimum ESR limit is encountered before the maximum capacitance value is reached.

#### 2.2.2 Ceramic Capacitors

Above 150 kHz, the performance of aluminum electrolytic capacitors is less effective. Multilayer ceramic capacitors have low ESR and a resonant frequency higher than the bandwidth of the regulator. They can be used to reduce the reflected ripple current at the input as well as improve the transient response of the output. When used on the output, their combined ESR is not critical as long as the total value of ceramic capacitance does not exceed approximately 300  $\mu\text{F}$ . Also, to prevent the formation of local resonances, do not place more than five identical ceramic capacitors in parallel with values of 10  $\mu\text{F}$  or greater.

#### 2.2.3 Capacitor Table

Table 2 identifies the characteristics of capacitors from a number of vendors with acceptable ESR and ripple current (rms) ratings. The recommended number of capacitors required at both the input and output buses is identified for each capacitor type.

*This is not an extensive capacitor list. Capacitors from other vendors are available with comparable specifications. Those listed are for guidance. The rms ripple current rating and ESR (at 100 kHz) are critical parameters necessary to insure both optimum regulator performance and long-term reliability.*

#### 2.2.4 Designing for Very Fast Load Transients

The transient response of the dc-dc converter has been characterized using a load transient with a di/dt of 1 A/ $\mu\text{s}$ . The typical voltage deviation for this load transient is given in the datasheet specification table using the optional value of output capacitance. As the di/dt of a transient is increased, the response of a converter regulation circuit ultimately depends on its output capacitor decoupling network. This is an inherent limitation with any dc-dc converter once the speed of the transient exceeds its bandwidth capability. If the target application specifies a higher di/dt or lower voltage deviation, the requirement can only be met with additional output capacitor decoupling. In these cases, special attention must be paid to the type, value, and ESR of the capacitors selected.

If the transient performance requirements exceed that specified in the datasheet, or the total amount of load capacitance is above 3,000  $\mu\text{F}$ , the selection of output capacitors becomes more important.

CAPACITOR VENDOR/ SERIES	CAPACITOR CHARACTERISTICS					QUANTITY		VENDOR PART NUMBER

Table 3 - Pin Connections

### 3.3 Pin Description

#### 3.3.1 Ground

This is the common ground connection for the  $V_{in}$  and  $V_{out}$  power connections. It is also the 0 Vdc reference for the control inputs.

#### 3.3.2 Vout

The regulated positive power output with respect to the GND node.

#### 3.3.3 Vo Adjust

A 1% tolerance (or better) resistor must be connected directly between this pin and pins 1 or 2 (GND) pin to set the output voltage to the desired value. The set point range for the output voltage is from 1.2 Vdc to 5.5 Vdc for the 'W' Suffix model and 0.8 Vdc to 1.8 Vdc for the 'L' Suffix model. If left open circuit, the module output will default to its lowest output voltage value.

The specification table gives the preferred resistor values for a number of standard output voltages.

#### 3.3.4 Track

This is an analog control input that allows the output voltage to follow another voltage during power-up and power-down sequences. The pin is active from 0 V up to the nominal set-point voltage. Within this range the module's output will follow the voltage at the Track pin on a volt-for-volt basis. When the control voltage is raised above this range, the module regulates at its nominal output voltage. If unused, this input maybe left unconnected. For further information consult Section 10.

Note: Due to the undervoltage lockout feature, the output of the module cannot follow its own input voltage during power up.

#### 3.3.5 Inhibit

The Inhibit pin is an open-collector/drain negative logic input that is referenced to GND. Applying a low level ground signal to this input disables the module's output and turns off the output voltage. When the Inhibit control is active, the input current drawn by the regulator is significantly reduced. If the Inhibit pin is left open-circuit, the module will produce an output whenever a valid input source is applied.

#### 3.3.6 Vin

The positive input voltage power node to the module, which is referenced to common GND.

#### 3.3.7 Vo Sense

The sense input allows the regulation circuit to compensate for voltage drop between the module and the load. For optimal voltage accuracy Vo Sense should be connected to Vo. It can also be left disconnected.

## 4. Packaging Information

### 4.1 Packaging

The PTV12020 are packaged individually in anti-static bags and then in anti-static foam in boxes of 84 pieces.

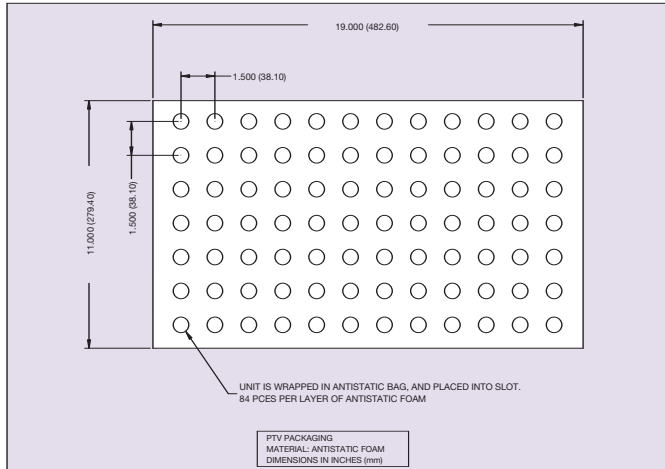

Figure 2 - Packaging Drawing

### 4.2 Labels and Part Numbering Sequence

All units in the series will be clearly marked to allow ease of identification for the end user. Figure 3 gives details of all the models.

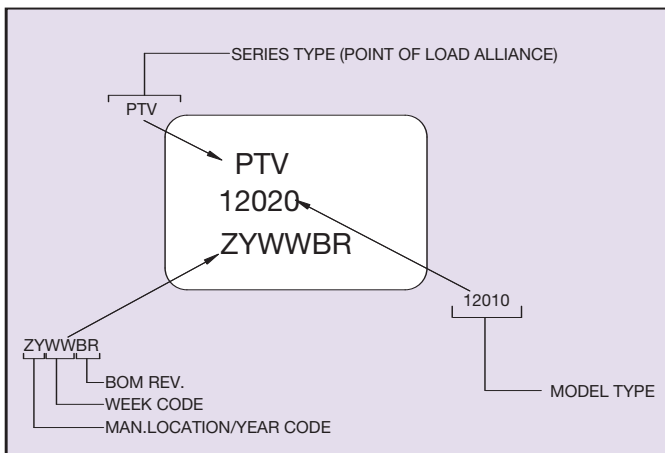

Figure 3 - PTV12020 Part Numbering

## 5. Safety Information

### 5.1 Safety Standards and Approvals

All models will have full international safety approval including EN60950 and UL/cUL1950. Models have been submitted to independent safety agencies for approval.

### 5.2 Fuse Information

Any suitable value fuse (based on the input ratings) maybe used in the unearthed input line. However this is not required for compliance with safety.

### 5.3 Safety Considerations

The converter must be installed as per guidelines outlined by the various safety agency approvals, if safety agency approval is required for the overall system.

## 6. Operating Information

### 6.1 Overtemperature Protection (OTP)

An onboard temperature sensor protects the module internal circuitry against excessively high temperatures. A rise in the internal temperature may be the result of a drop in airflow or a high ambient temperature. If the internal temperature exceeds the OTP threshold, the module Inhibit control is internally pulled low. This turns the output off. The output voltage drops as the external output capacitors are discharged by the load circuit. The recovery is automatic, and begins with a soft-start power up. It occurs when the sensed temperature decreases by about 10 °C below the trip point.

Note: The overtemperature protection is a last resort mechanism to prevent thermal stress to the regulator. Operation at or close to the thermal shutdown temperature is not recommended and reduces the long-term reliability of the module. Always operate the regulator within the specified Safe Operating Area (SOA) limits for the worst-case conditions of ambient temperature and airflow.

### 6.2 Overcurrent Protection (OCP)

For protection against load faults, the modules incorporate output overcurrent protection. Applying a load that exceeds the overcurrent threshold causes the regulated output to shut down. Following shutdown, a module periodically attempts to recover by initiating a soft-start power-up. This is described as a hiccup mode of operation, whereby the module continues in the cycle of successive shutdown and power-up until the load fault is removed. During this period, the average current flowing into the fault is significantly reduced. Once the fault is removed, the module automatically recovers and returns to normal operation.

### 6.3 Soft-Start Power-Up

The Auto-Track feature allows the power-up of multiple PTH/PTV modules to be directly controlled from the Track pin. However, in a stand-alone configuration, or when the Auto-Track feature is not being used, the Track pin should be directly connected to the input voltage,  $V_I$  (see Figure 4).

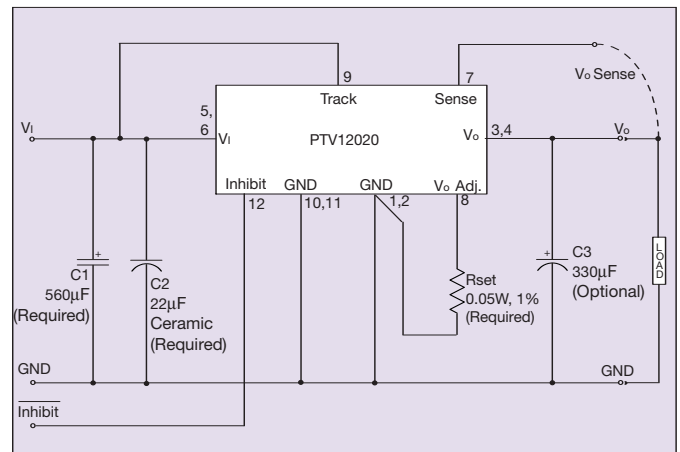

Figure 4 - Soft-Start Power-up

When the Track pin is connected to the input voltage, the Auto-Track function is permanently disengaged. This allows the module to power-up entirely under the control of its internal soft-start circuitry. When power-up is under soft-start control, the output voltage rises to the set-point at a quicker and more linear rate.

Figure 5 - Power-up Characteristic

From the moment a valid input voltage is applied, the soft-start control introduces a short time delay (typically 8 ms to 15 ms) before allowing the output voltage to rise. The output then progressively rises to the module's setpoint voltage. Figure 5 shows the soft-start power-up characteristic of the PTV12010W, operating from a 12 V input bus and configured for a 3.3 V output. The waveforms were measured with a 5 A resistive load and the Auto-Track feature disabled. The initial rise in input current when the input voltage first starts to rise is the charge current drawn by the input capacitors. Power-up is complete within 25 ms.

## 7. Feature Set

### 7.1 Adjusting the Output Voltage

The  $V_o$  adjust control (pin 8) sets the output voltage of the PTV12020 product. The adjustment range is from 1.2 Vdc to 5.5 Vdc for the Suffix 'W' models and from 0.8 Vdc to 1.8 Vdc for the Suffix 'L' models. The adjustment method requires the addition of a single external resistor,  $R_{set}$ , that must be connected directly between the  $V_o$  adjust and GND pins 1 or 2. Tables 4b and 4c give the preferred value for the external resistor for a number of standard voltages, along with the actual output voltage that this resistance value provides. Figure 6 shows the placement of the required resistor.

For other output voltages the value of the required resistor can either be calculated using the following formula, or simply selected from the range of values given in Tables 5a and 5b. The Equation below may be used for calculating the adjust resistor value. Select the appropriate value for the parameters,  $R_s$  and  $V_{min}$ , from Table 4a.

Pt. No.	PTV12010W	PTV12010L
$V_{min}$	1.2 V	0.8 V
$V_{max}$	5.5 V	1.8 V
$R_s$	1.82 V	7.87 k $\Omega$

$$R_{set} = 10\text{ K} \times \frac{0.8\text{ V}}{V_{out} - V_{min}} - R_s\text{ k}\Omega$$

Table 4a - Adjust Formula Parameters

$V_{out}$ Standard	$R_{set}$ (Preferred Value)	$V_{out}$ (Actual)
5.0 V	280 $\Omega$	5.009 V
3.3 V	2.0 k $\Omega$	3.294 V
2.5 V	4.32 k $\Omega$	2.503 V
2.0 V	8.06 k $\Omega$	2.010 V
1.8 V	11.5 k $\Omega$	1.801 V
1.5 V	24.3 k $\Omega$	1.506 V
1.2 V	Open	1.200 V
1.1 V	N/A	N/A
1.0 V	N/A	N/A
0.9 V	N/A	N/A
0.8 V	N/A	N/A

Table 4b - Preferred Values of  $R_{set}$  for Standard Output Voltages Suffix 'W' Models

$V_{out}$ Standard	$R_{set}$ (Preferred Value)	$V_{out}$ (Actual)
5.0 V	N/A	N/A
3.3 V	N/A	N/A
2.5 V	N/A	N/A
2.0 V	N/A	N/A
1.8 V	130 $\Omega$	1.800 V
1.5 V	3.57 k $\Omega$	1.499 V
1.2 V	12.1 k $\Omega$	1.201 V
1.1 V	18.7 k $\Omega$	1.101 V
1.0 V	32.4 k $\Omega$	0.999 V
0.9 V	71.5 k $\Omega$	0.901 V
0.8 V	Open	0.800 V

Table 5b - Output Voltage Set-point Resistor Values for Suffix 'L' Model

**Notes:**

- 1 A 0.05 W rated resistor may be used. The tolerance should be 1 %, with temperature stability of 100 ppm/°C (or better). Place the resistor as close to the regulator as possible. Connect the resistor between pin 8 and pins 1 or 2, using dedicated PCB traces.
- 2 Never connect capacitors from Vo Adjust to either GND or Vout. Any capacitance added to the Vo Adjust pin will affect the stability of the regulator.

**7.2 Output ON/OFF Inhibit**

For applications requiring output voltage ON/OFF control, each series of the PTH/PTV family incorporates an output Inhibit control pin. The inhibit feature can be used wherever there is a requirement for the output voltage from the regulator to be turned OFF.

The power modules function normally when the Inhibit pin is left open-circuit, providing a regulated output whenever a valid source voltage is connected to Vin with respect to GND. Figure 7 shows the typical application of the inhibit function. Note the discrete transistor (Q1). The Inhibit control has its own internal pull-up to +Vin potential. An open-collector or open-drain device is recommended to control this input.

Turning Q1 on applies a low voltage to the Inhibit control pin and disables the output of the module. If Q1 is then turned off, the module will execute a soft-start power-up sequence. A regulated output voltage is produced within 25 ms. Figure 8 shows the typical rise in both the output voltage and input current, following the turn-off of Q1. The turn off of Q1 corresponds to the rise in the waveform, Q1 V<sub>DS</sub>. The waveforms were measured with a 5 A load.

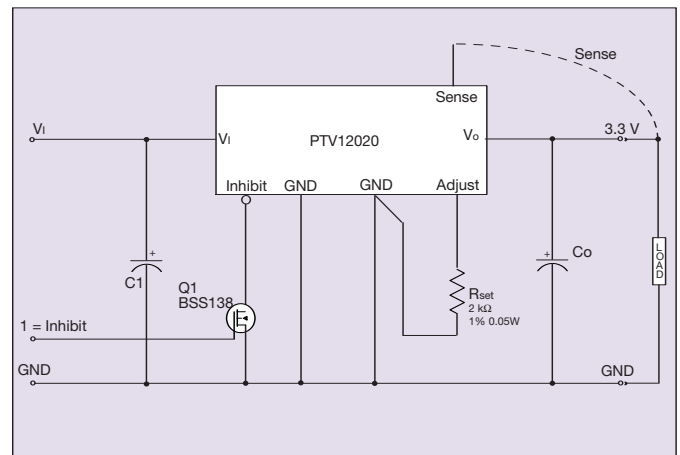

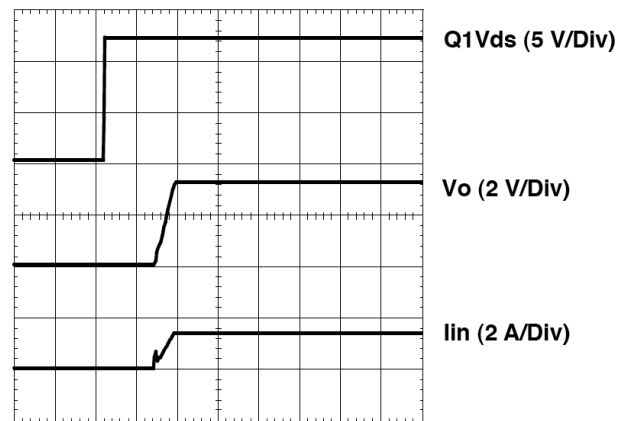

Figure 7 - Typical Application of the Inhibit Function

HORIZ SCALE: 10 ms/Div

Figure 8 - Typical Rise in Output Voltage and Input Current

**Notes**

- 1 The pre-bias start-up feature is not compatible with Auto-Track. If the rise in the output is limited by the voltage applied to the Track control pin, the output sinks current during the period that the track control voltage is below that of the back-feeding source. For this reason, Auto-Track should be disabled when not being used. This is accomplished by connecting the Track pin to the input voltage,  $V_i$ . This raises the Track pin well above the set-point. voltage prior to start-up, thereby defeating the Auto-Track feature.
- 2 To further ensure that the regulator output does not sink current when power is first applied (even with a ground signal applied to the Inhibit control input), the input voltage must always be greater than the applied pre-bias source. This condition must exist throughout the power-up sequence of the power system.

**8. Thermal Information**

**8.1 Thermal Reference Points**

The electrical operating conditions namely:

- Input voltage,  $V_{in}$
- Output voltage,  $V_o$
- Output current,  $I_o$

determine how much power is dissipated within the converter. The following parameters further influence the thermal stresses experienced by the converter:

- Ambient temperature
- Air velocity
- Thermal efficiency of the end system application
- Parts mounted on system PCB that may block airflow
- Real airflow characteristics at the converter location

**8.2 Safe Operating Area Curve**

Thermal characterisation data is presented in the datasheet in a safe operating area curve format which are repeated here in Figures 12a and 12b. This SOA curve shows the load current versus the ambient air temperature and velocity.

**Figure 12b - Safe Operating Curve  
PTV12010L  $V_{out} = 3.3 V$**

**8.3 Thermal Test Set-up**

All of the data was taken with the converter soldered to a test board which closely represents a typical application. The test board is a 1.6 mm, eight layer FR4 pcb with the inner layers consisting of 2 oz power and ground planes. The top and bottom layers contain a minimal amount of metalisation. A board to board spacing of 1 inch was used. The data represented by the 0 m/s curve indicate a natural convection condition i.e. no forced air. However, since the thermal performance is heavily dependent upon the final system application, the user needs to ensure the thermal reference point temperatures are kept within the recommended temperature rating. It is recommended that the thermal reference point temperatures are measured using either AWG #36 or #40 gauge thermocouples or an IR camera. In order to comply with stringent Artesyn de-rating criteria, the ambient temperature should never exceed 85 °C. Please contact Artesyn Technologies for further support.

**9. Use in a Manufacturing Environment**

**9.1 Recommended Land Pattern**

It is recommended that the customer uses a solder mask defined land pattern similar to that shown in Figure 13.

**Figure 12a - Safe Operating Curve  
PTV12010W  $V_{out} = 5.0 V$**

**Figure 13 - Recommended Land Pattern**

Power pin connection should utilize four or more vias to the interior power plane of 0.025 (0.63) I.D. per input, ground and output pin (or the electrical equivalent).

## 10. Auto-Track™

### 10.1 Auto-Track™ Function

The Auto-Track function is unique to the PTH/PTV family, and is available with all POLA products. Auto-Track was designed to simplify the amount of circuitry required to make the output voltage from each module power-up and power down in sequence. The sequencing of two or more supply voltages during power-up is a common requirement for complex mixed-signal applications that use dual-voltage VLSI ICs such as DSPs, microprocessors, and ASICs.

### 10.2 How Auto-Track™ Works

Auto-Track works by forcing the module output voltage to follow a voltage presented at the Track control pin<sup>(1)</sup>. This control range is limited to between 0 V and the module set-point voltage. Once the track-pin voltage is raised above the set-point voltage, the module's output remains at its set-point<sup>(2)</sup>. As an example, if the Track pin of a 2.5 V regulator is at 1 V, the regulated output is 1 V. But if the voltage at the Track pin rises to 3 V, the regulated output does not go higher than 2.5 V.

When under Auto-Track control, the regulated output from the module follows the voltage at its Track pin on a volt-for-volt basis. By connecting the Track pin of a number of these modules together, the output voltages follow a common signal during power-up and power down. The control signal can be an externally generated master ramp waveform, or the output voltage from another power supply circuit<sup>(3)</sup>. For convenience, the Track input incorporates an internal RC-charge circuit. This operates off the module input voltage to produce a suitable rising waveform at power-up

### 10.3 Typical Application

The basic implementation of Auto-Track allows for simultaneous voltage sequencing of a number of Auto-Track compliant modules. Connecting the Track control pins of two or more modules forces the Track control of all modules to follow the same collective RC-ramp waveform, and allows them to be controlled through a single transistor or switch; see Q1 in Figure 14.

To initiate a power-up sequence, it is recommended that the Track control first be pulled to ground potential. This is done at or before input power is applied to the modules, and then held for at least 10 ms thereafter. This brief period gives the modules time to complete their internal soft-start initialization. Applying a logic level high signal to the circuit On/Off Control turns Q1 on and applies a ground signal to the Track input of the modules. After completing their internal soft-start initialization, the output of all modules remains at zero volts while Q1 is on.

Q1 may be turned off 10 ms after a valid input voltage has been applied to the modules. This allows the track control voltage to automatically rise to the module input voltage. During this period, the output voltage of each module rises in unison with other modules to its respective set-point voltage.

Figure 15 shows the output voltage waveforms from the circuit of Figure 14 after the On/Off Control is set from a high-level to a low-level voltage. The waveforms,  $V_{O1}$  and  $V_{O2}$  represent the output voltages from the two power modules, U1 (3.3 V) and U2 (1.8 V), respectively.  $V_{O1}$  and  $V_{O2}$  are shown rising together to produce the desired simultaneous power-up characteristic.

The same circuit also provides a power-down sequence. Power down is the reverse of power-up, and is accomplished by lowering the track control voltage back to zero volts. The important constraint is that a valid input voltage must be maintained until the power down is complete. It also requires that Q1 be turned off relatively slowly. This is so that the Track control voltage does not fall faster than Auto-Track slew rate capability, which is 1 V/ms. The components R1 and C1 in Figure 14 limit the rate at which Q1 pulls down the Track control voltage. The values of 100 k $\Omega$  and 0.1  $\mu$ F correlate to a decay rate of about 0.17 V/ms.

The power-down sequence is initiated with a low-to-high transition at the On/Off Control input to the circuit. Figure 16 shows the power-down waveforms. As the Track control voltage falls below the nominal set-point voltage of each power module, then its output voltage decays with all the other modules under Auto-Track control.

### Notes of the Use Auto-Track™

- 1 The Track pin voltage must be allowed to rise above the module set-point voltage before the module can regulate at its adjusted set-point voltage. voltage prior to start-up, thereby defeating the Auto-Track feature.
- 2 The Auto-Track function tracks almost any voltage ramp during power-up, and is compatible with ramp speeds of up to 1 V/ms.
- 3 The absolute maximum voltage that may be applied to the Track pin is the input voltage  $V_I$ .
- 4 The module cannot follow a voltage at its Track control input until it has completed its soft-start initialization. This takes about 10 ms from the time that a valid voltage has been applied to its input. During this period, it is recommended that the Track pin be held at ground potential.
- 5 The module is capable of both sinking and sourcing current when following a voltage at its Track input. Therefore, start up into an output pre-bias cannot be supported when a module is under Auto-Track control.

**Note:** A pre-bias holdoff is not necessary when all supply voltages rise simultaneously under the control of Auto-Track.

- 6 The Auto-Track function can be disabled by connecting the Track pin to the input voltage ( $V_I$ ). When Auto-Track is disabled, the output voltage rises at a quicker and more linear rate after input power has been applied.
